Is a mutant U3 snRNA gene a defect in the mouse oocyte maturation? Oocytes from mice carrying a non-functioning U3 snRNA gene contained a reduced number of RNA polymerase II molecules associated with transcribed ribosomal RNA genes. Hence, U3-encoded snRNAs are required for the initiation of RNA polymerase II transcription in mouse oocytes. We have studied the phenotype of mice lacking a functional U3 snRNA gene. Homozygous mutant oocytes undergo metaphase II at the normal time of occurrence and are capable of in vitro maturation and ovulation. However, the number of nuclear, cytoplasmic and mitochondrial DNA molecules was reduced in homozygous mutant oocytes as compared with those from control heterozygous mice. This decrease was associated with a drastic reduction of the oocyte size. The impaired size of the mutant oocyte may be due to a selective growth of the granulosa cells, because an abnormally high level of FSH was present in mutant females before meiosis I. The induction of meiosis was not affected in mutant oocytes. In conclusion, we have shown that a single gene mutation in the U3 snRNA gene in mice resulted in two major defects: (i) a defect in the maturation of the oocyte that may result from a preferential growth of the granulosa cells; and (ii) a defect in the initiation of RNA polymerase II transcription in oocytes.1. Field of the Invention The present invention relates to a lithographic apparatus and a method for manufacturing a device. 2. Description of the Related Art A lithographic apparatus is a machine that applies a desired pattern onto a substrate, usually onto a target portion of the substrate. A lithographic apparatus can be used, for example, in the manufacture of integrated circuits (ICs). In that instance, a patterning device, which is alternatively referred to 82157476af
